# The Standard Model of Physics

## Quarks

## Leptons

## Forces

An *extremely successful* theory, stood up to experimental tests for over 30 years.

“The theory of *almost* everything”

Includes all known fundamental particles, gives rise to every element in the periodic table.

A very economical model of 3 fundamental forces:

- Strong nuclear
- Electromagnetic
- Weak nuclear

# The Standard Model of Physics

## Quarks

## Leptons

H  
Higgs  
boson

## Forces

Bosons are the  
carriers of the  
fundamental forces

An *extremely successful* theory, stood up to experimental tests for over 30 years.

“The theory of *almost* everything”

Includes all known fundamental particles, gives rise to every element in the periodic table.

A very economical model of 3 fundamental forces:

- Strong nuclear
- Electromagnetic
- Weak nuclear

# The Standard Model of Physics

## Quarks

## Leptons

## Forces

The Higgs boson: the last particle predicted by the SM.  
Something very close to it was observed at the LHC.

Yet another SM prediction verified by experiment (?)

So then why look for physics *beyond the Standard Model, since it's been so successful?*

# The problems with the Standard Model

- **Major omissions**

What about gravity? Dark matter?

- **Experimental tests**

Neutrino oscillations. Discrepancies with experimental **precision** tests (muon g-2)

- **Naturalness, hierarchy**

Gravity is  $\sim 10^{32}$ x weaker than the weak, fine-tuning required

- **Too many free parameters**

Up to 25 free parameters in the SM: how fundamental is *that*?

Is the SM just an effective theory at low energies, just like Newtonian gravity to General Relativity?

Is there an **underlying symmetry** at higher energies?

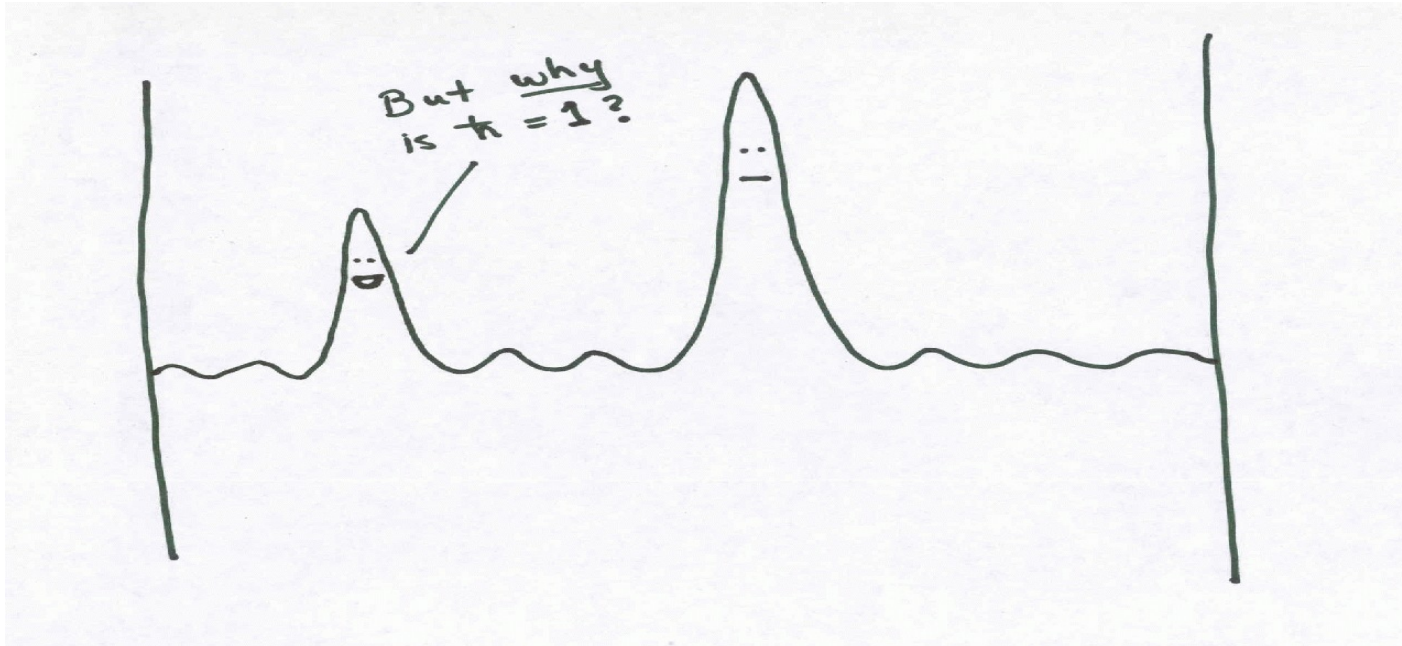

How can precision experiments at low energies probe for new physics?  
A SuperSymmetric example

Of course, we could be wrong..

The parameters of the Standard Model *could* have been chosen randomly.

Only in a small subset of potential universes can living intelligence arise to ask annoying questions:

But the Anthropic Principle is a dead-end observation, not a strategy for learning.  
We choose to learn.

The concept of **symmetry** has guided our thought in understanding nature and searching for new physics

Example:

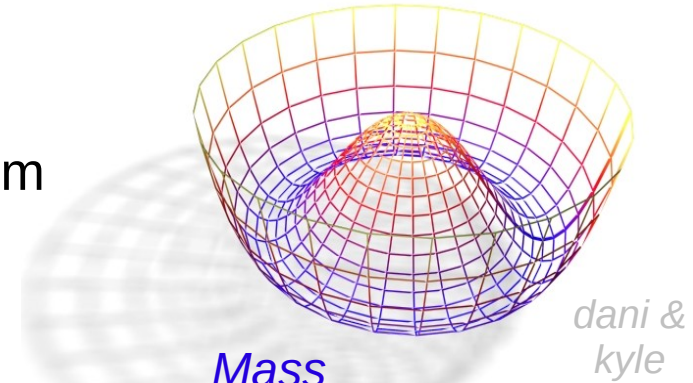

Electricity and Magnetism, once thought to be distinct phenomena.

Their symmetry was *hidden* from us until we found they are just “two sides of the same coin”

Another example of a hidden/broken symmetry:  
**Electro-Weak symmetry**

Underlying symmetry: **Electro-Weak unification**  
 Broken at low energies through the *Higgs* mechanism

<i>Interaction</i>	<i>Carrier</i>	<i>Field</i>	<i>Mass</i>
EM	Photon	$A_\mu = B_\mu^0 \cos \theta_W + W_\mu^0 \sin \theta_W$	Massless
(Neutral) Weak	Z boson	$Z_\mu = W_\mu^0 \cos \theta_W - B_\mu^0 \sin \theta_W$	91.2 GeV

Underlying symmetry: **Electro-Weak unification**  
 Broken at low energies through the *Higgs* mechanism

dani &  
kyle

<i>Interaction</i>	<i>Carrier</i>	<i>Field</i>	<i>Mass</i>
EM	Photon	$A_\mu = B_\mu^0 \cos \theta_W + W_\mu^0 \sin \theta_W$	Massless
(Neutral) Weak	Z boson	$Z_\mu = W_\mu^0 \cos \theta_W - B_\mu^0 \sin \theta_W$	91.2 GeV

*Combinations of the same fields!*

*The weak mixing angle,  $\theta_w$*

A fundamental parameter of the EW sector of the SM

## Interlude:

How do precision experiments at low energies access physics beyond the Standard Model?

Quantum fluctuations: “*Virtual*” particles may jump out of the “*vacuum*”

Simple exchange of  $Z$  between an  $e^-$  and a  $q$

Must account for more complicated processes with “quantum loops”, allowed from the uncertainty principle:

All these contributions should be calculable within the theory, if our theory is complete

If a **precision** experiment finds discrepancy with theory, this may be a sign of new physics, even well below the energy scale associated with the new physics.

Higher energies

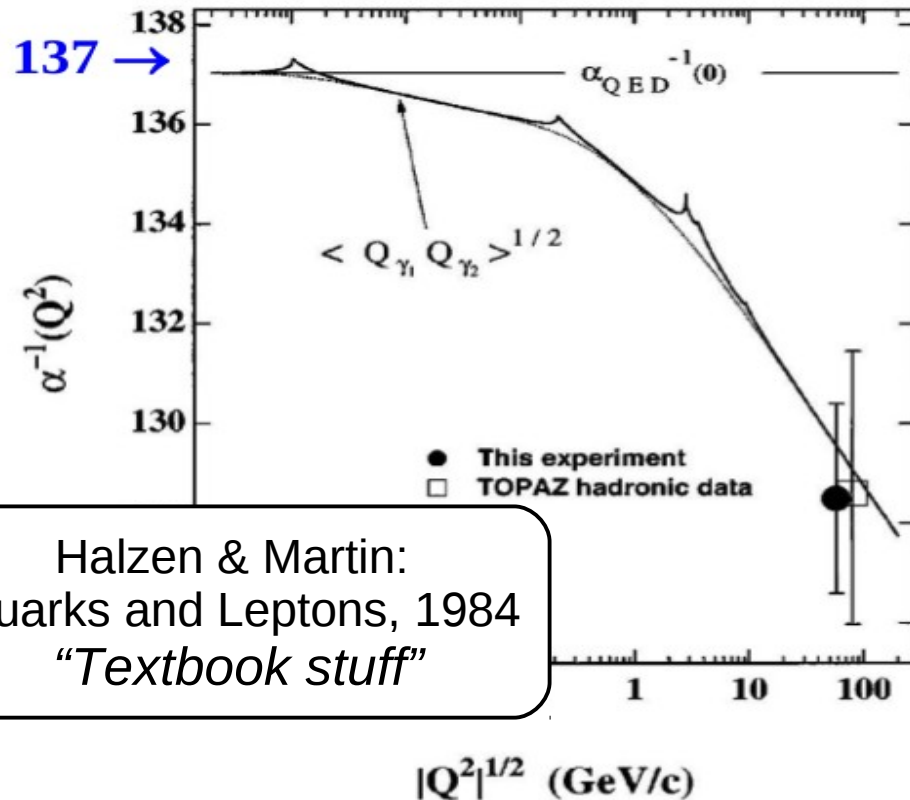

- Smaller time and length scales
- Contribution from quantum fluctuations depends on available energy

“Running” of fundamental constants: not constants at all!

QED:  
Screening

Halzen & Martin:  
Quarks and Leptons, 1984  
“Textbook stuff”

QCD:  
Anti-Screening

What about the Weak constant?

# The Weak Mixing Angle

SM prediction

Current world data from:

- Z-pole measurements from colliders (LEP, SLD)
- ν-N scattering
- Moller scattering
- Atomic Cs transition

“Running” of  $\sin^2\theta_w$  in the  $\overline{\text{MS}}$  scheme

# The Weak Mixing Angle

The Qweak experiment will measure  $\sin^2\theta_w$  to 0.3% precision at low  $Q^2$ :

- Most precise determination off the Z-pole
- A 10-sigma confirmation of the predicted “running”
- A unique testing ground for the SM

*Agreement with theory would impose significant constraints on possible SM extensions*

*A significant deviation could be a signal of new physics at the quantum loop level, with sensitivity up to the TeV scale (complimentary to LHC searches)*

- ▶ *The Standard Model of Physics*
- ▶ *The  $Q_{\text{weak}}$  experiment*
- ▶ First results
- ▶ Summary, outlook

# *The Qweak experiment at Jefferson Lab*

---

Qweak ran in Hall C  
of Jefferson Lab  
in Newport News, Va

Completed May 2012  
after 2 years of data taking

The Thomas Jefferson  
National Accelerator Facility  
World-leading **Parity Violation** program

*Qweak will make the first determination of the neutral weak charge of the proton*, the weak analog to the electric charge:

Charge Particle	Electric	Weak (vector)
u	+2/3	$-2 C_{1u} = +1 - 8/3 \sin^2 \theta_W$
d	-1/3	$-2 C_{1d} = -1 + 4/3 \sin^2 \theta_W$
<i>Proton</i> uud	+1	$Q_W^p = 1 - 4 \sin^2 \theta_W \approx 0.07$
<i>Neutron</i> udd	0	$Q_W^n = -1$

} Suppressed

Because of this suppression, a 4% determination of  $Q_W^p$  allows a 0.3% extraction of  $\sin^2 \theta_W$

→ *TeV-scale sensitivity to new physics*

Experimental probe:  
electron-proton scattering

EM or weak interaction,  
exchange of a photon or a Z boson

$$\sigma \propto |M_{EM} + M_{Weak}|^2 \approx M_{EM}^2 + 2M_{EM}M_{Weak}$$

$$|M_{EM}| / |M_{weak}| \approx 10^4$$

But the weak amplitude is hopelessly  
swamped by the EM part!

→ Access the weak part of the interaction through *Parity Violation*

Parity is the symmetry under space inversion,  
equivalent to a mirror reflection

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} \Rightarrow \begin{pmatrix} -x \\ -y \\ -z \end{pmatrix} := \begin{pmatrix} x \\ y \\ -z \end{pmatrix}$$

All fundamental forces were thought to be  
symmetric under parity, until the 1956 Wu  
experiment: Beta emission from Co nuclei in  
magnetic field

Expected (in 1956)

Parity is the symmetry under space inversion,  
equivalent to a mirror reflection

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} \Rightarrow \begin{pmatrix} -x \\ -y \\ -z \end{pmatrix} := \begin{pmatrix} x \\ y \\ -z \end{pmatrix}$$

Parity symmetry is *violated*  
in weak interactions!

(1957 Nobel Prize  
Lee and Yang)

Observed

Parity violation is used to access the weak part of the e-p interaction.

Electrons are prepared in two states of opposite helicity ( $\boldsymbol{\sigma} \cdot \mathbf{p}$ ), the two “mirror” states.

Then the *Parity-Violating Asymmetry* in the scattering rate is due to the weak interaction

$$A_{PV} = \frac{\sigma_R - \sigma_L}{\sigma_R + \sigma_L} \approx \frac{2|M_{Weak}|}{|M_{EM}|}$$

Asymmetry still very small ( $\sim 0.3$  parts-per-million) and challenging to measure. Precision measurements using parity violation only possible with recent technological advances.

# The Qweak Apparatus

180  $\mu$ A  $e^-$  beam,  
1.165 GeV  
89% polarization  
1 ms helicity flip

R helicity

L helicity

Magnetic field  
bends elastically  
scattered  $e^-$  to  
the main  
detector

2.5 kW LH2 target,  
highest power  
cryotarget in the  
world

Collimator system  
selects  $e^-$

forward angles

Main detector:  
Azimuthally symmetric  
array of 8 Cerenkov bars

# *The Qweak Apparatus*

Sep 23, 2013

First Determination of the Weak Charge of the Proton

- ▶ *The Standard Model of Physics*
- ▶ The Qweak experiment
- ▶ *First results*
- ▶ Summary, outlook

- First Qweak results released recently  
(now in print in PRL - [arxiv.org/abs/1307.5275](https://arxiv.org/abs/1307.5275))
- Only 4% of full dataset, taken over a few days during commissioning
- Some subsystems were still in commission;  
Systematic uncertainties very conservative

# Wien0 Hydrogen Elastic Asymmetry and Corrections

$$A_{ep} = R_{tot} \frac{A_{msr}/P - \sum_{i=1}^4 f_i A_i}{1 - \sum f_i}$$

Measured asymmetry must be first corrected and normalized

$R_{tot}$ : Radiative corrections, kinematics normalization  
 $P$ : Polarization  
 $f_i$ : Fraction of bkgd in signal (aka "dilution")  
 $A_i$ : Asymmetry of bkgd

$$A_{msr} = -204 \pm 34 \text{ ppb} \quad (16.5\% \text{ rel})$$

$$A_{ep} = -279 \pm 35 \text{ (stat)} \pm 31 \text{ (syst)} \text{ ppb} \quad (16.8\% \text{ rel})$$

# Wien0 Hydrogen Elastic Asymmetry and Corrections

$$A_{ep} = R_{tot} \frac{A_{msr}/P - \sum_{i=1}^4 f_i A_i}{1 - \sum f_i}$$

*Smallest  
asymmetry and  
smallest absolute  
error bar ever  
measured in  
e-p scattering*

$$A_{msr} = -204 \pm 34 \text{ ppb} \quad (16.5\% \text{ rel})$$

$$A_{ep} = -279 \pm 35 \text{ (stat)} \pm 31 \text{ (syst)} \text{ ppb} \quad (16.8\% \text{ rel})$$

Qweak measurement,  
error bars barely  
visible

A and  $\Delta A$  are  $\sim 3\times$   
smaller than nearest  
competitor.

# First determination of the neutral-weak charge of the proton, $Q_w^p$

$Q_w^p$  can be extracted from the PV asymmetry:

$$\overline{A_{LR}^p} = A_{LR}^p / A_0 = \underline{Q_w^p} + Q^2 \boxed{B(Q^2)}, \quad A_0 = \frac{-G_F Q^2}{4\pi\alpha\sqrt{2}} \quad (\text{Forward angles, low } Q^2)$$

*Hadronic structure enters here.*  
Sufficiently constrained from world  
PVES data and suppressed at  
Qweak kinematics.

Low  $Q^2$  means that  $Q_w^p$  can be  
extracted relatively cleanly.

# First determination of the neutral-weak charge of the proton, $Q_w^p$

$$A/A_0 = Q_w^p + Q^2 B(Q^2)$$

Global fit:

$$Q_w^p = 0.064 \pm 0.012$$

The Qweak point significantly shifts the result of the global fit and reduces the uncertainty

Increased consistency with SM value:

$$Q_w^p(SM) = 0.0710 \pm 0.0007$$

# Constraints on $C_{1q}$ couplings

$$L_{e-q}^{PV} = \frac{G_F}{\sqrt{2}} \bar{e} \gamma_\mu \gamma^5 e \sum_q \underline{C_{1q}} \bar{q} \gamma^\mu q$$

$C_{1q}$ : Vector quark couplings

$$Q_w^p = -2 (2C_{1u} + C_{1d})$$

PVES has sensitivity to a  $C_{1u}, C_{1d}$  combination that is orthogonal to APV

# Constraints on $C_{1q}$ couplings

Combining APV + PVES,  
global constraints on  $C_{1q}$ :

$$C_{1u} = -0.184 \pm 0.005$$

$$C_{1d} = 0.335 \pm 0.005$$

From these the weak  
charge of the neutron is  
extracted for the first time:

$$Q_w^n = -2 (2C_{1d} + C_{1u})$$

$$\Rightarrow Q_w^n = -0.975 \pm 0.010$$

In agreement with SM value:

$$Q_w^n(SM) = -0.9890 \pm 0.0007$$

# Weak mixing angle

$$Q_W(p) = [\rho_{NC} + \Delta_e][1 - 4 \sin^2 \hat{\theta}_W(0) + \Delta'_e] + \square_{WW} + \square_{ZZ} + \square_{\gamma Z}$$

- Theoretical background,  
Motivation for the  $Q_{\text{weak}}$  measurement
- An overview of the  $Q_{\text{weak}}$  experiment
- First results:  
The 25% measurement
- **Summary, Outlook**

# Summary

---

Qweak has achieved the first determination of the weak charge of the proton, with 4% of the data set

~25 times more statistics and additional calibration data are in hand for the full Qweak measurement; analysis ongoing

Full measurement will extend reach to the TeV-scale and constrain scenarios for physics *beyond the Standard Model*

The experiment achieved and demonstrated the technological base for future ultra-precision tests planned at the upgraded Jefferson Lab

# Outlook

# Outlook

# Outlook

Next generation of experiments planned to test the EW sector of the SM.

Moller, SOLID:  
Ultra-precision measurements planned in the upgraded 12GeV Jefferson Lab, after Qweak demonstrated sufficient control of systematics.

## *Backup Slides*

A “new physics” term in the Lagrangian  
(approximating by a 4-fermion contact interaction) :

$$\begin{aligned}\mathcal{L}_{e-q}^{PV} &= \mathcal{L}_{SM}^{PV} + \boxed{\mathcal{L}_{New}^{PV}} \\ &= -\frac{G_F}{\sqrt{2}} \bar{e} \gamma_\mu \gamma_5 e \sum_q C_{1q} \bar{q} \gamma^\mu q + \frac{g^2}{4\Lambda^2} \bar{e} \gamma_\mu \gamma_5 e \sum_q h_V^q \bar{q} \gamma^\mu q\end{aligned}$$

$$\frac{\text{Mass}}{\text{Coupling}} \quad \frac{\Lambda}{g} \approx \frac{1}{\sqrt{\sqrt{2} G_F} |\Delta Q_W(p)|} \approx 4.6 \text{ TeV}$$

*Sensitivity to new physics up to the TeV scale*  
(thanks to suppression of  $Q_W(p)$  in the SM)

Complementarity with searches at the intensity frontier:  
In the event of a discovery at the LHC, precision experiments like Qweak will be very important to determine the characteristics of the new interaction.

## First determination of the neutral-weak charge of the proton, $Q_w^p$

---

$$Q_w^p = 0.064 \pm 0.012$$

Even with only 4% of the full data set,  $Q_{\text{weak}}$  significantly constrains new physics scenarios.

*Model independent mass reach (95% CL) comparable to LHC limits:*

Mass scale over  
coupling of new physics

$$\frac{\Lambda}{g} \approx \frac{1}{\sqrt{\sqrt{2} G_F |\Delta Q_w^p|}} \sim 2.2 \text{ TeV}$$

Strongly coupled theories have  $g^2 \sim 4\pi$ .  
Separate limits can be quoted for models that interfere constructively and destructively with the Standard Model.

# Liquid Hydrogen target

- Long (35cm) LH2 target
- Extreme cooling requirements due to large beam heat load
- *Highest power cryotarget in the world: 2.5kW*
- Design based on Computational Fluid Dynamics to reduce density fluctuations

Target Cell

Fluid velocity

Fluid density

# Error Budget

Uncertainty	$\Delta A_{PV}/A_{PV}$	$\Delta Q_W/Q_W$
Statistical (~2,5k hours at 150 $\mu$ A)	2.1%	3.2%
<b>Systematic:</b>		<b>2.7%</b>
Hadronic structure uncertainties	---	1.5%
Beam polarimetry	1.0%	1.5%
Absolute $Q^2$ determination	0.5%	1.0%
Backgrounds	0.5%	0.7%
Helicity correlated beam properties	0.5%	0.8%
<b>Total:</b>	<b>2.5%</b>	<b>4.2%</b>

Error budget corresponds to a  $\sim 0.3\%$  determination of  $\sin^2\theta_W$ ,  
including uncertainties from higher order corrections:

$$Q_W(p) = [\rho_{NC} + \Delta_e][1 - 4 \sin^2 \hat{\theta}_W(0) + \Delta'_e] + \square_{WW} + \square_{ZZ} + \square_{\gamma Z}$$

# Polarimetry

Qweak requirement:  $dP/P = 1\%$

Two independent measurements:

Moller Polarimeter  
Requires dedicated  
low-current running

Compton Polarimeter  
Installed by the collaboration  
for continuous polarimetry

Consistency among independent measurements

Fabry-Perot cavity  
fabricated by UVA  
UVA Polarimetry group  
maintained the laser and  
the photon detector

# Impact on quark weak charges

1302.6263v1 [hep-ex] (2013)

# Polarized source at Jefferson Lab

Main source of helicity correlated differences: relative residual linear light coupled with an asymmetric transport.

UVA Source group responsible for alignment and optimization, achieved excellent suppression of HC differences in the injector although optimum settings would drift.

# Beamline Background Asymmetry

Hypothesis: Asymmetric “beam halo” interacts with the tungsten plug and the beamline

Different background detectors see asymmetries proportional to the background fraction in their signal

Quite large background asymmetries make this an important correction

## Background asymmetries

Continuous monitoring from background detectors

Sep 23, 2013

First Determination of the Weak Charge of the Proton
